Smart Logistics System Diagrams

These rendered diagrams explain current runtime boundaries and source-backed request flows. Solid lines indicate implemented routing or data paths; the optional companion-service model is described explicitly rather than assumed active in every browser workflow.

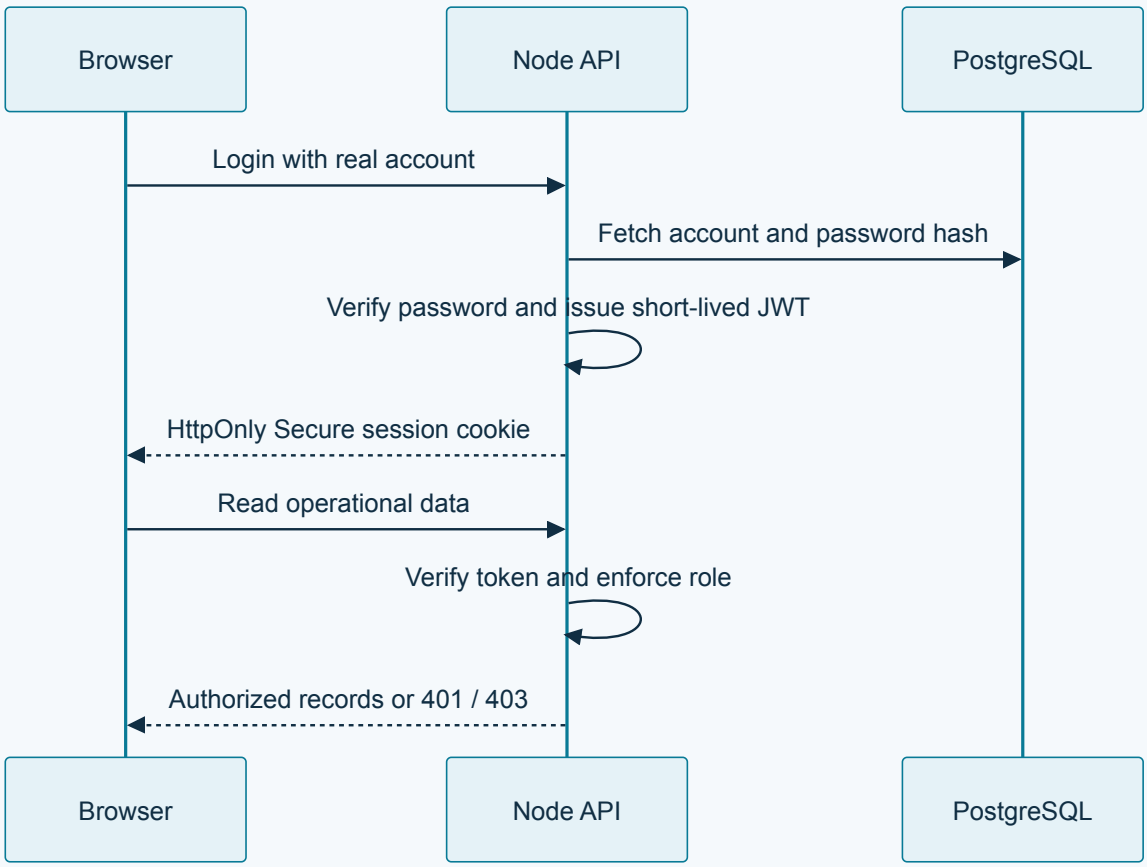

1. Runtime and trust boundaries

1. Runtime and trust boundaries · Open the diagram for a full-size view.

Browser operations use the Node API. The gateway and .NET service foundation are packaged alongside it. A deployment template for an Azure dependency is not evidence that the live application uses it. Caddy terminates HTTPS and internal service ports remain private.

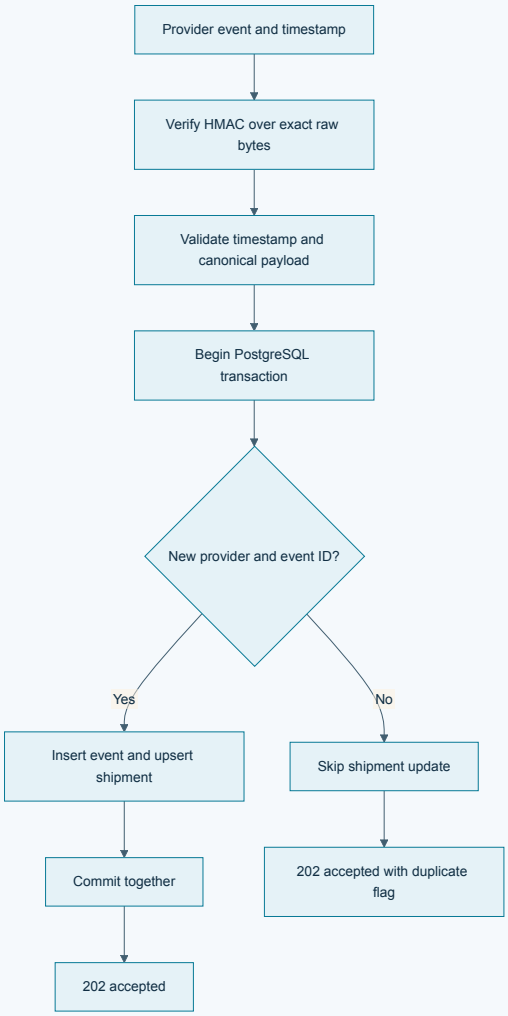

2. Real-account authentication

2. Real-account authentication · Open the diagram for a full-size view.

Demo authentication is a separate browser adapter. The real-account flow verifies token issuer, audience, expiry, and role server-side. UI visibility alone does not grant access.

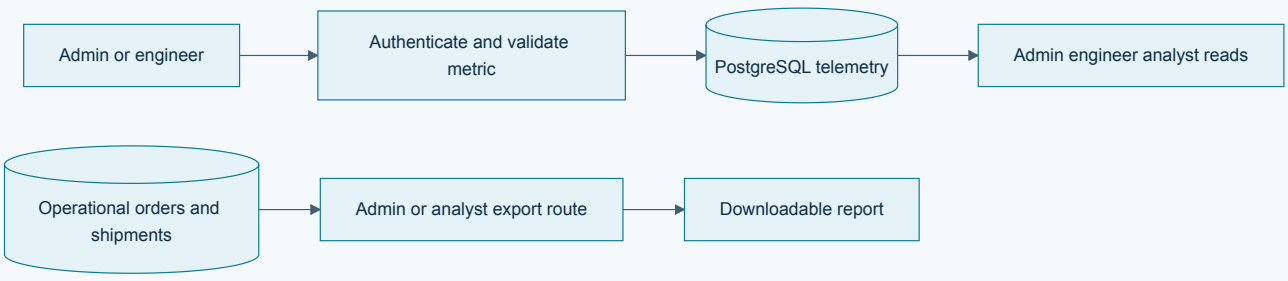

3. Logistics event consistency

3. Logistics event consistency · Open the diagram for a full-size view.

Idempotency uses a unique provider/event key. A tracking number identifies the shipment. The handler does not order events by occurrence time, so late events need integration-level handling.

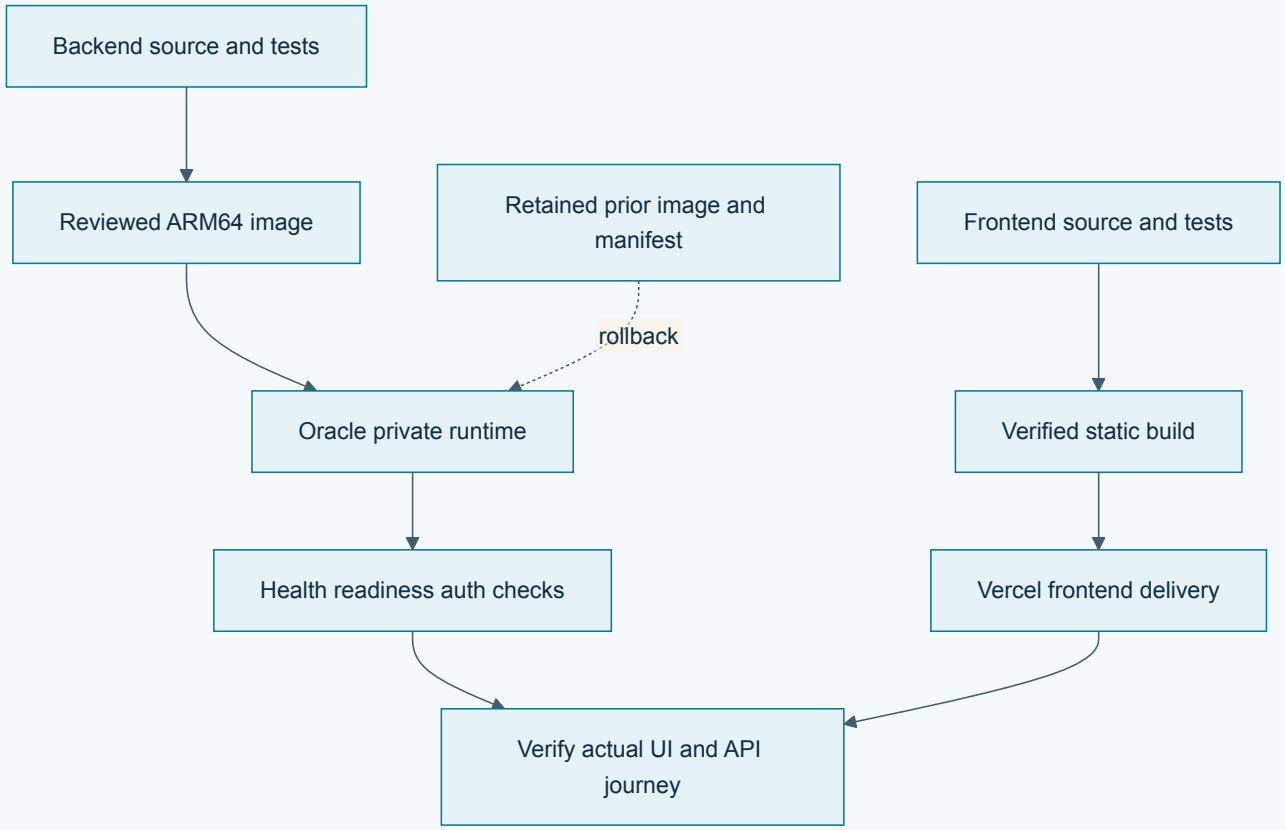

4. Telemetry and reporting

4. Telemetry and reporting · Open the diagram for a full-size view.

Telemetry uses authenticated REST ingestion; it does not imply a commissioned MQTT or factory-control connection. Samples use server storage timestamps, while logistics records retain provider occurrence and API receipt timestamps.

5. Independent release and recovery

5. Independent release and recovery · Open the diagram for a full-size view.

Backend updates are manual and independent from frontend releases. Restore a compatible tested image on failed acceptance; recover incompatible database changes through a separate restore plan.
